

## Beta\_p estimations vs rq() coefficients on NMES1988

```
response = NMES1988[,1] # Number of physician office visits.
dat = NMES1988[c(8,11,15,16)] # Remove the responses

# Center and scale the continuous predictors:
# dat[c(2,4)] = scale(dat[c(2,4)])
```

### NMES1988 Dataset

The data was sourced from US National Medical Expenditure Survey [NMES] data for 1987/88. Available as NMES1988 in package AER (Kleiber and Zeileis 2008). Originally taken from Deb and Trivedi (J. Applied Econometrics 1997)

## Beta\_p estimations vs rq() coefficients

The plot titles are formatted as (sampling method)(*quantile*)(error distribution)\_(beta\_p). The histograms are the beta\_p estimations yielded by the paper's model. The red horizontal line reflects rq() beta coefficients. The absence of red lines in some plots reflects big difference in our beta\_p estimations and the rq() results.

### Notations:

GWS: Gibbs sampler of the asymmetric Laplace distribution (ALD) with Scale parameter

GWOS: Gibbs sampler of the asymmetric Laplace distribution (ALD) without Scale parameter

stdN: Standard Normal Prior

beta\_1: Intercept

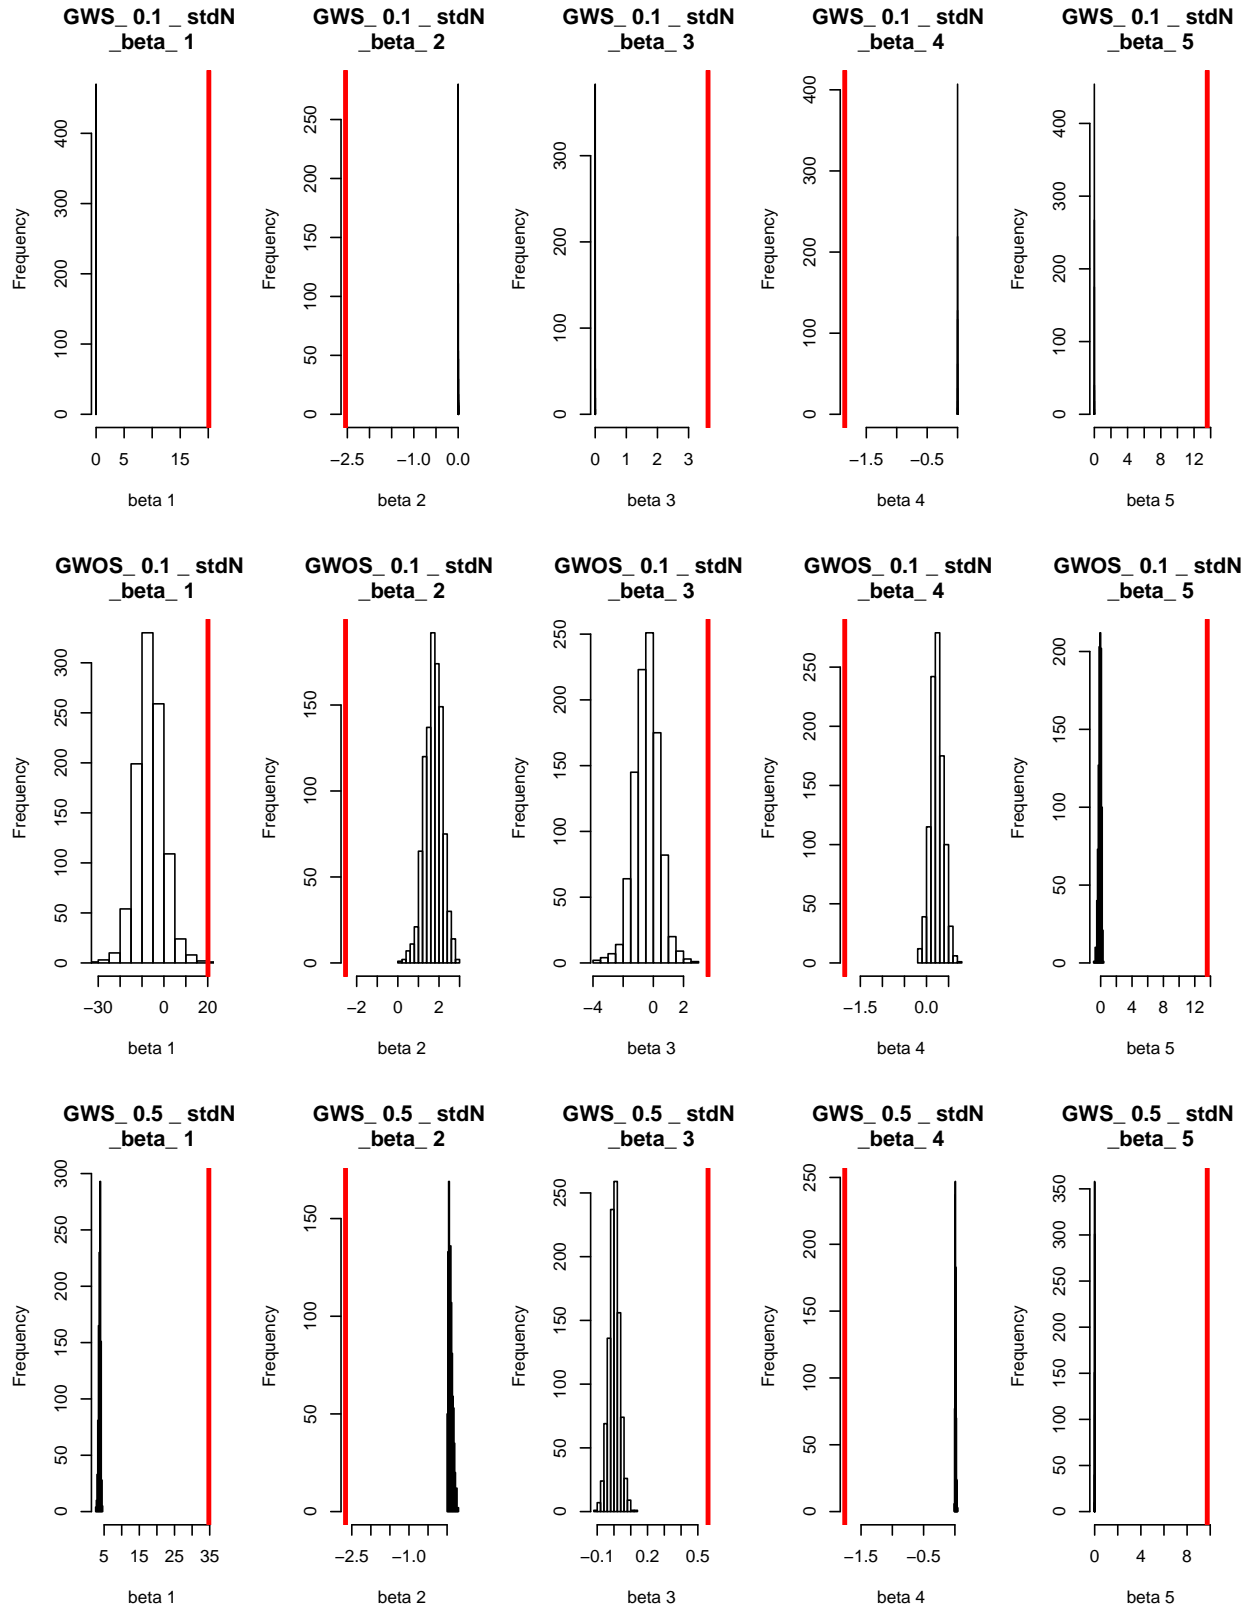

beta\_2: Regression coefficient associated with chronic

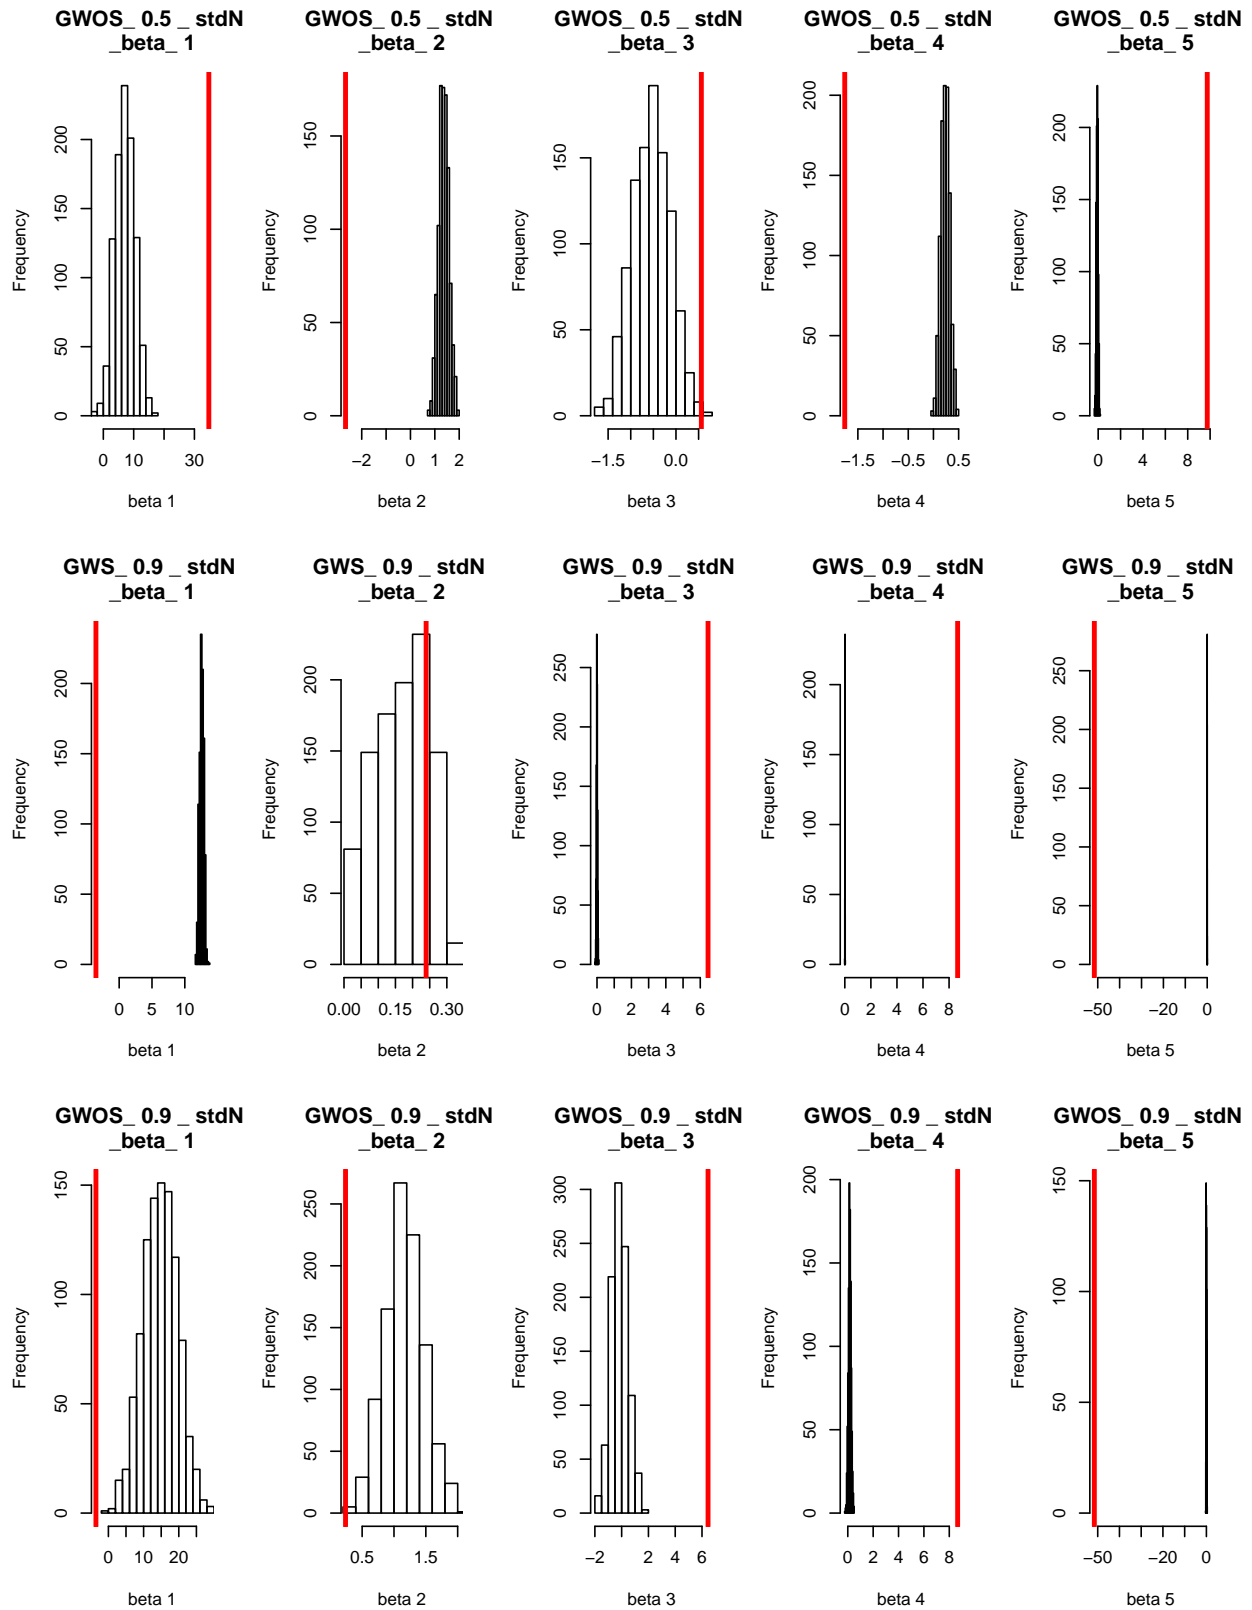

beta\_3: Regression coefficient associated with age

beta\_4: Regression coefficient associated with school

beta\_5: Regression coefficient associated with income
